Photoshop and Photoshop Elements offer more manual control than their competitors. You can change many types of image characteristics through mouse clicks, and not just by adjusting sliders, color wheels and curves. Unlike the rest, Photoshop and Photoshop Elements offer many features for free, such as retouching and fixing flaws. You can use these alternatives to any extent you want, though most people only use basic features. You can find great alternatives to Photoshop and Photoshop Elements at Best Apps (site discontinued). If you are looking for a new photo editor then check out the alternatives below. Powerful alternatives to Adobe Photoshop Adobe Photoshop and Photoshop Elements are the most popular for most graphic designers, photographers and hobbyists. Both are available for both Mac and Windows operating systems.

Cable broadcast systems including, but not limited to, systems operating in accordance with standards such as ATSC, DVB-S, and IEEE 802.11n, and other wireless broadcast systems include one or more antennas to provide radio coverage to one or more locations in the coverage area. The performance of the broadcast system may be improved if the antenna is electronically steerable to provide the desired coverage. Typically, antenna beam steering is performed using a technique called amplitude and phase (AP) beamforming. For AP beamforming, the transmitter may transmit a signal to the antenna using a plurality of phases. For example, a transmitter may transmit data using one or more phases in either the in-phase (I) component and/or the quadrature (Q) component of the signal. The beamforming weights are selected and then applied to the phased signal(s). These weighted signal(s) are then summed and transmitted from the antenna. Ideally, the antenna only transmits signals in the desired direction and only attenuates signals transmitted in undesired directions. However, in reality the antenna often transmits some amount of energy into the undesired direction(s). To better understand the functioning of an AP beamforming transmitter, consider the function of a simple single element, linear phase, down-tilt antenna. In this scenario, the signals in the I and Q components may be linearly processed, as illustrated in FIG. 1. In this example, component I is processed using a phase voltage of $V_p = V_c \cos(2\pi ft + \Phi_p)$ and component Q is processed using a phase voltage of $V_q = V_c \sin(2\pi ft + \Phi_q)$, where Φ_p , Φ_q , f , V_c , and t are parameters. In this example, for simplicity, the amplitudes of the carrier signal $V_{in} = \sqrt{V}$ and noise n_{in} are not shown, but amplitudes of this type may be included if desired. Now assume that the phase of component Q is shifted relative to component I by Φ_d . For example, if the phase of component Q is shifted clockwise by 1.5π and the phase of component I is not altered, then component Q will be delayed and will take place after component I, as illustrated in FIG. 2A. As the antenna receives the signals, the beamforming weights are applied to the I and Q component signals. The weighted sum of these components is then amplified and transmitted.
